RAW MILK FACT SHEET

Raw milk is milk that has not been pasteurized before consumption. The Food and Drug Administration (FDA) and the Centers for Disease Control and Prevention (CDC) recommend drinking only pasteurized milk, because raw milk may contain harmful bacteria such as E. coli O157:H7, Listeria and Salmonella that can cause life-threatening illnesses. This recommendation has been affirmed by the American Medical Association and the American Academy of Pediatrics, among others.

Raw Milk and the Law

Because raw milk, by nature, may contain harmful bacteria such as E. coli O157:H7, Listeria and Salmonella that can cause life-threatening illnesses, it is a violation of federal law to sell raw milk for consumer use across state lines. However, raw milk regulations vary by state, and some states allow the sale of raw milk within their borders. This means that, in some states, raw milk may be sold to local retail food stores or directly from the farm to consumers.¹

Risks of Raw Milk Consumption

The American Academy of Pediatrics (AAP) warns of the serious risks for children who consume raw milk. Similarly, pregnant women, the elderly, and those with compromised immune systems should not consume raw milk.² Before the invention and acceptance of pasteurization, raw milk was a common source of bacteria that caused serious illnesses such as tuberculosis, diphtheria, and typhoid fever. In the 1900s, many mothers recognized this risk and would boil milk before giving it to their infants and young children.

According to the Food and Drug Administration, there were at least 143 outbreaks due to the consumption of raw milk and raw milk products in the U.S. from 1987 to October 2011.³ Between 1987 and September 2010, outbreaks caused 2,659 cases of illnesses, 269 hospitalizations, three deaths, six stillbirths and two miscarriages. Because not all cases of foodborne illness are recognized and reported, the actual number of illnesses associated with raw milk likely is greater.⁴

According to a review of 13 years of information by the Centers for Disease Control and Prevention, the rate of outbreaks caused by raw milk and products made from it was 150 times greater than outbreaks linked to pasteurized milk. The review also revealed that:

- States where the sale of raw milk was legal had more than twice the rate of outbreaks as states where it was illegal.

- Outbreaks led to much more severe illnesses. Thirteen percent of patients in raw milk outbreaks were hospitalized compared to 1 percent in pasteurized milk outbreaks. This may be because raw milk outbreaks were all caused by bacteria, such as E. coli O157, which tend to produce more severe illnesses, according to the study.

- People under the age of 20 were disproportionately affected. Children are more likely than adults to get seriously ill from the bacteria in raw milk.⁵
The Importance of Pasteurization

Pasteurization is a simple, effective method that kills the harmful pathogens found in raw milk. Since its introduction more than a century ago, pasteurization has been recognized around the world as an essential tool for ensuring that milk and dairy foods are safe. During pasteurization, the temperature of milk is raised to 145° for 30 minutes or to at least 161° Fahrenheit for more than 15 seconds; it is then rapidly cooled. In addition to helping extend milk’s shelf-life, this process destroys many harmful bacteria, including Salmonella, Campylobacter and Listeria. Some dairy foods are pasteurized using the “ultra-high temperature” method, which is particularly effective in extending shelf-life. This process heats milk to 280° Fahrenheit for more than two seconds, and this processed milk may have a caramel-like flavor. Because of pasteurization, less than 1.5 percent of annual foodborne illness outbreaks in the United States involve dairy foods.6

While pasteurization has helped provide safe, nutrient-rich dairy products for over 100 years, some people continue to believe that pasteurization harms milk and that raw milk is a safe, healthier alternative. Here are some proven facts about milk and pasteurization:

In 1924, the U.S. Public Health Service developed a regulation known as the Standard Milk Ordinance; the ordinance was adopted by both local and state milk-control agencies. This regulation is known today as the “Grade ‘A’ Pasteurized Milk Ordinance” (PMO). It is periodically reviewed and modified in cooperation with state and local governments, the dairy industry, and educational and research institutions. All 50 states have voluntarily adopted the PMO guidelines, which establish maximum allowable bacterial limits in pasteurized milk.

Nutritional Value and Safety

There is no scientific evidence to suggest that there is any meaningful difference in the nutritional value of pasteurized and unpasteurized (raw) milk.8 In addition, vitamin D, which is not found in significant amounts in raw milk, is added to processed milk, making it an even more nutritious product. Vitamin D insufficiency and deficiency is a common problem in the United States affecting many Americans, especially those of Hispanic or African American descent. The addition of vitamin D makes pasteurized milk an excellent source of this essential nutrient, providing 25% of the daily value in one 8-ounce serving.

Pasteurization does not affect a person’s ability to digest lactose, the sugar present in milk. The enzyme required to break down lactose, known as lactase, is produced by cells that line the small intestine in the human body. This enzyme is not present in either raw or pasteurized milk.

Dairy foods are among the most tested and regulated foods in the United States. In addition to the extensive and rigorous safety and quality tests that dairy foods go through before they reach the grocery store, dairy farms and plants must meet stringent federal and local regulations, including those developed by the U.S. Department of Agriculture, the FDA, and other state regulatory agencies.

The FDA advises consumers to be alert when they buy milk or milk products.7 To avoid raw milk, here are a few things the FDA suggests:

- Read the label on milk or milk products before you buy them. Many companies put the word “pasteurized” right on the label, but it is not required by law.
- Ask store employees if specific brands are pasteurized.
• At farm stands or farmers’ markets, ask if the milk and cream being sold have been pasteurized. If the market sells yogurt, ice cream, or cheese, ask if they were made with pasteurized milk.

These groups endorse the importance of pasteurization and warn against raw milk consumption:9

• American Academy of Pediatrics
• American Medical Association
• American Veterinary Association
• Association of Food and Drug Officials
• Centers for Disease Control and Prevention
• Health Canada
• International Association of Food Protection
• National Association of State Public Health Veterinarians
• National Environmental Health Association
• U.S. Food and Drug Administration
• World Health Organization
